We've decided to add another piece of functionality, which is going to be an explore page that renders all of the items in the database, this is going to be tough because it's pretty easy to grab posts that are listed under a particular class with the way our database is set up. Grabbing all the posts is going to require some custom logic in order to format it correctly so that I can ship it off as one object to the BuyList class to be rendered on screen.

(I)

How to post all content in DB?

plan: create some sort of looping structure to grab all the posts in the db

(M)

create an array of all the values in the listings that are in db and then loop based on the size of the array. Inside of that array, loop again to get each post inside of that class and store it in an object outside of the loop.

Reflect: that took a lot of console.log() to see what I was working with but after a lot of trial and error I can now list all the content in the database. Can't sort it in anyway but I'll come back to that later if I get the time.
